## 1 Derived Categories

## 1 Derived Categories

In this note, we will sketch some proofs but not in detailed.

**Definition 1.1.** Let  $\mathcal{C}$  be a category. A category  $\mathcal{D}$  is a *subcategory* of  $\mathcal{C}$  if the  $\text{Ob}(\mathcal{D})$  and the  $\text{Hom}_{\mathcal{D}}(X, Y)$  are subcollections of  $\text{Ob}(\mathcal{C})$  and  $\text{Hom}_{\mathcal{C}}(X, Y)$ , respectively, for all objects  $X$  and  $Y$  in  $\mathcal{C}$ . The subcategory  $\mathcal{D}$  is said to be *full* if for all objects  $X$  and  $Y$  in  $\mathcal{D}$ ,  $\text{Hom}_{\mathcal{D}}(X, Y)$  is exactly  $\text{Hom}_{\mathcal{C}}(X, Y)$ .

**Definition 1.2.** Let  $\mathcal{C}$  be a category. A morphism  $f : A \rightarrow B$  is a *monomorphism* if for all  $g, h : C \rightarrow A$ ,  $f \circ g = f \circ h$  implies  $g = h$ . A morphism  $f : A \rightarrow B$  is called an *epimorphism* if for all  $i, j : B \rightarrow D$ ,  $i \circ f = j \circ f$  implies  $i = j$ .

**Definition 1.3.** Let  $\mathcal{C}$  be a category. A morphism  $f : X \rightarrow Y$  in  $\mathcal{C}$  is a *constant morphism* if for all object  $Z$  and morphisms  $g, h : Z \rightarrow X$ ,  $fg = fh$ . A morphism is a *zero morphism* if it is both a constant morphism and a coconstant morphism.

**Definition 1.4.** Let  $\mathcal{C}$  be a category. A *kernel* of a morphism  $f : X \rightarrow Y$  is a pair  $(K, k)$ , where  $K$  is an object and  $k : K \rightarrow X$  is a morphism, such that

1.  $fk = 0_{KY}$ .
2. For all  $(K', k')$  such that  $k'f = 0_{K'Y}$ , there exists a unique  $u : K' \rightarrow K$ .

**Definition 1.5.** Let  $F$  and  $G$  be functors between  $\mathcal{C}$  and  $\mathcal{D}$ . A *natural transformation*  $\eta$  from  $F$  to  $G$  is a family of morphisms such that

1. For all object  $X$  in  $\mathcal{C}$ , there exists a morphism  $\eta_X : F(X) \rightarrow G(X)$ , called the *component* at  $X$ .
2. For all  $f : X \rightarrow Y$ ,  $\eta_Y \circ F(f) = G(f) \circ \eta_X$ .

A functor  $F : \mathcal{C} \rightarrow \mathcal{D}$  is a *natural functor* if for all  $G : \mathcal{C} \rightarrow \mathcal{D}$ , there exists a natural transformation  $\eta$ .

**Definition 1.6.** A category  $\mathcal{C}$  is an *additive category* if every hom-set of  $\mathcal{C}$  is an abelian group, composition of morphisms is bilinear, and  $\mathcal{C}$  admits finite coproduct.

**Definition 1.7.** A functor  $f : \mathcal{A} \rightarrow \mathcal{B}$  between additive categories is an *additive functor* if it preserves the finite coproduct.

**Definition 1.8.** A category  $\mathcal{C}$  is a *pre-abelian category* if  $\mathcal{C}$  is an additive category and every morphism in  $\mathcal{C}$  has a kernel and a cokernel. A pre-abelian category  $\mathcal{C}$  is an *abelian category* if every monomorphism is a kernel and every epimorphism is a cokernel.

**Definition 1.9.** Let  $\mathcal{A}$  be an additive category. A *cochain complex* is a collection  $X^*$  of objects  $X^n$  in  $\mathcal{A}$  with maps  $d^n : X^n \rightarrow X^{n+1}$  such that  $d^{n+1}d^n = 0$ . The morphism between complexes  $X^*$  and  $Y^*$  is a collection of maps  $f^n : X^n \rightarrow Y^n$  such that  $f^{n+1}d_X^n = d_Y^n f^n$ . This defines the category of cochain complexes, denoted  $\mathcal{C}(\mathcal{A})$ .

**Definition 1.10.** Let  $X^*$  and  $Y^*$  be cochain complexes. The maps  $f, g : X^* \rightarrow Y^*$  are *homotopic* if there exists a collection of maps  $k^n : X^n \rightarrow Y^{n-1}$  such that  $f^n - g^n = d_Y^{n-1}k^n + k^{n+1}d_X^n$ .

It is trivial that homotopy is an equivalence relation.

**Definition 1.11.** Let  $\mathbf{A}$  be an additive category. The objects of the *homotopy category*, denoted  $K(\mathbf{A})$ , are cochain complexes and the morphisms are homotopic class of morphisms of cochain complexes.

Let  $\mathbf{A}$  be an additive category and  $K(\mathbf{A})$  be the homotopy category. Define the finite coproduct to be the direct sum  $(X^* \oplus Y^*)^n = X^n \oplus Y^n$ . Define the composition to be pairwise addition. Since composition in  $\mathbf{A}$  is bilinear, it is bilinear in  $K(\mathbf{A})$ . It is not hard to check that  $K(\mathbf{A})$  is additive.

**Definition 1.12.** A *triangulated category* is an additive category  $\mathbf{C}$  with:

1. an additive automorphism  $T : \mathbf{C} \rightarrow \mathbf{C}$  called the *translation functor*,
2. a collection of *triangles*  $(X, Y, Z, u, v, w)$ , where  $X, Y$ , and  $Z$  are objects of  $\mathbf{C}$  and  $u : X \rightarrow Y$ ,  $v : Y \rightarrow Z$ , and  $w : Z \rightarrow T(X)$  are morphisms,
3. morphisms  $(f, g, h) : (X, Y, Z, u, v, w) \rightarrow (X', Y', Z', u', v', w')$  such that the following diagram commutes.

$$\begin{array}{ccccccc}
 X & \xrightarrow{u} & Y & \xrightarrow{v} & Z & \xrightarrow{w} & T(X) \\
 \downarrow f & & \downarrow g & & \downarrow h & & \downarrow T(f) \\
 X' & \xrightarrow{u'} & Y' & \xrightarrow{v'} & Z' & \xrightarrow{w'} & T(X')
 \end{array}$$

The data subject to the following rules:

1. The sextuple  $(X, X, 0, \text{id}_X, 0, 0)$  is a triangle and for all  $f : A \rightarrow B$ , there exists a triangle  $(A, B, C, f, g, h)$ .
2. A sextuple  $(A, B, C, f, g, h)$  is a triangle if and only if  $(B, C, T(A), g, h, -T(f))$  is a triangle.
3. Let  $(X, Y, Z, u, v, w)$  and  $(X', Y', Z', u', v', w')$  be triangles. Let  $f : X \rightarrow X'$  and  $g : Y \rightarrow Y'$  be morphisms in  $\mathbf{C}$  that commutes with  $u$  and  $u'$ , then there exists  $h : Z \rightarrow Z'$  such that  $(f, g, h)$  is a morphism between triangles.

$$\begin{array}{ccccccc}
 X & \xrightarrow{u} & Y & \longrightarrow & Z & \longrightarrow & T(X) \\
 \downarrow f & & \downarrow g & & \downarrow h & & \downarrow T(f) \\
 X' & \xrightarrow{u'} & Y' & \longrightarrow & Z' & \longrightarrow & T(X')
 \end{array}$$

4. Let  $(X, Y, Z', u, j, )$ ,  $(Y, Z, X', v, , i)$ , and  $(X, Z, Y', vu, , )$  be triangles, then there exists morphisms  $f : Z' \rightarrow Y'$  and  $g : Y' \rightarrow X'$  such that  $(Z', Y', X', f, g, T(j)i)$  is a triangle and the following diagram commutes.

$$\begin{array}{ccc}
 Z' & \xrightarrow{\quad f \quad} & Y' \\
 \downarrow & \swarrow & \downarrow \\
 X & & X'
 \end{array}
 \qquad
 \begin{array}{ccc}
 Y' & \xleftarrow{\quad g \quad} & Z \\
 \downarrow & \swarrow & \downarrow \\
 X' & & X
 \end{array}$$

This is called the *octohedral axiom*.

$$\begin{array}{ccccc}
 & & Y' & & \\
 & \swarrow f & & \searrow g & \\
 Z' & & & & X' \\
 \downarrow & & \downarrow T(j)i & & \downarrow \\
 X & & & & Z \\
 \swarrow u & & \searrow v & & \\
 & & Y & & 
 \end{array}$$

**Definition 1.13.** Let  $\mathcal{C}$  and  $\mathcal{D}$  be additive categories. An additive functor  $f : \mathcal{C} \rightarrow \mathcal{D}$  is a *covariant  $\partial$ -functor* if it commutes with the translation functor and it preserves triangles. A *contravariant  $\partial$ -functor* takes triangles into triangles with the arrows reversed, and sends the translation functor into its inverse.

Homotopy categories can be triangulated.

**Proposition.** Let  $T(X^*)^p = X^{p+1}$  and  $d_{T(X)} = -d_X$ . Given a morphism  $u : X^* \rightarrow Y^*$ , we define  $Z^*$  to be the *mapping cone*  $T(X^*) \oplus Y^*$ . The differential maps in  $Z^*$  are matrices  $\begin{pmatrix} T(d_X) & T(u) \\ 0 & d_Y \end{pmatrix}$ . We pick  $v : Y^* \rightarrow Z^*$  and  $w : Z^* \rightarrow X^*$  to be the natural inclusion and projection. A triangle is defined to be a sextuple that induces by a morphism  $u : X^* \rightarrow Y^*$ . This defines a triangulated category.

*Proof.* (TR1) Take  $\text{id}_X : X^* \rightarrow X^*$ , then  $Z^* = T(X^*) \oplus X^*$  and the differentials are  $d_Z^n = \begin{pmatrix} -d_X^n & \text{id}_{X^{n+1}} \\ 0 & d_X^n \end{pmatrix}$ . Define  $k^n : Z^n \rightarrow Z^{n-1}$  by  $k^n((a, b)) = (0, a)$ . Then  $k^{n+1}d_Z^n((a, b)) = k^{n+1}((-d_X^n(a) + b, d_X^n(b))) = (0, -d_X^n(a) + b)$  and  $d_Z^{n-1}k^n((a, b)) = d_Z^{n-1}((0, a)) = (a, d_X^n(a))$ . We have  $(k^{n+1}d_Z^n + d_Z^{n-1}k^n)((a, b)) = (a, b)$ , hence  $\text{id}_Z \sim 0$ . The sextuple  $(X, X, 0, \text{id}_X, 0, 0)$  is the triangle induced by  $\text{id}_X : X^* \rightarrow X^*$ .  $\square$  (TR2) Let  $(X^*, Y^*, Z^*, u, v, w)$  be a triangle. Denote  $T(Y^*) \oplus Z^*$  by  $A^*$ . Consider the sextuple  $(Y^*, Z^*, A^*, v, s, t)$ ,  $\square$

**Definition 1.14.** Let  $\mathcal{C}$  be a category and let  $S$  be a collection of morphisms in  $\mathcal{C}$ , then the *localization* of  $\mathcal{C}$  with respect to  $S$  is a category  $\mathcal{C}_S$  together with a functor  $Q : \mathcal{C} \rightarrow \mathcal{C}_S$  such that

1.  $Q(s)$  is an isomorphism for every  $s \in S$ .
2. Any functor  $F : \mathcal{C} \rightarrow \mathcal{D}$  such that  $F(s)$  is an isomorphism for all  $s \in S$  factors uniquely through  $Q$ .

If  $Q' : \mathcal{C} \rightarrow \mathcal{C}_S$  is another functor satisfies these properties, then the two localizations are considered to be equivalent.

**Definition 1.15.** Let  $\mathbf{A}$  be an abelian category. A *quasi-isomorphism* is a morphism  $f : X^* \rightarrow Y^*$  in  $\mathbf{K}(\mathbf{A})$  which induces an isomorphism on cohomology. The collection of all quasi-isomorphisms is denoted by  $\text{Qis}$ .

**Definition 1.16.** The *derived category*  $\mathbf{D}(\mathbf{A})$  of an abelian category  $\mathbf{A}$  is the localization  $\mathbf{K}(\mathbf{A})_{\text{Qis}}$ .

**Proposition.** Given an abelian category  $\mathbf{A}$ , there exists a derived category  $\mathbf{D}(\mathbf{A})$ .

*Proof.* Consider the generalization: any localization  $\mathcal{C}_S$  exists. Let  $\text{Ob}(\mathcal{C}_S) = \text{Ob}(\mathcal{C})$  and let  $Q$  be the identity on objects. For all  $s \in S$ , introduce some variable  $x_s$ , then construct an oriented graph  $\Gamma$  as follows: let the vertices be objects in  $\mathcal{C}$ , let the edges be morphisms in  $\mathcal{C}$  union  $\{x_s\}$ , the edge has the direction  $X \rightarrow Y$  if there exists a morphism  $X \rightarrow Y$  in  $\mathcal{C}$ , and the edge  $x_s$  has the same vertices as the edges but the opposite orientation. Define a morphism to be an equivalence class of paths that share the same initial and terminal in  $\Gamma$ . Two paths are equivalent if they can be joined by a chain of elementary equivalences that two consecutive arrows in a path can be replaced by their composition and arrows  $X \xrightarrow{s} Y \xrightarrow{s_x} X$  can be replaced by  $X \xrightarrow{\text{id}_X} X$ . The composition of morphisms is induced by the conjunction of paths. The functor  $Q$  takes a morphism to a corresponding path of length 1. The inverse of a morphism  $s \in S$  is  $x_s$ . Suppose we have another functor  $\mathcal{C} \rightarrow \mathcal{C}'$  satisfies the universal property. We construct  $G : \mathcal{C}_S \rightarrow \mathcal{C}'$  by  $G(X) = F(X)$ ,  $G(f) = F(f)$ , and  $G((x_s)) = F(s)^{-1}$  for all  $X \in \text{Ob}(\mathcal{C})$ ,  $f \in \text{Mor}_{\mathbf{A}}$ , and  $s \in S$ . This defines a localization but we will not check the axioms here.  $\square$

Let  $s \in S$  and let  $f : X' \rightarrow Y$  be a morphism in  $\mathbf{A}$ . A *roof* is a diagram  $(s, f)$  of the form

$$\begin{array}{ccc} & X' & \\ s \swarrow & & \searrow f \\ X & & Y \end{array}$$

The morphisms in  $\mathcal{C}_S$  are equivalence classes of roofs. One could check this is exactly the same as we described in the previous proposition.

**Proposition.** Derived categories are additive.

*Proof.* Let  $\varphi, \varphi' : X \rightarrow Y$  be morphisms in  $\mathbf{D}(\mathbf{A})$ .

$$\begin{array}{ccc} & U & \\ t \swarrow & & \searrow g \\ X & & Y \end{array} \qquad \begin{array}{ccc} & U' & \\ t' \swarrow & & \searrow g' \\ X & & Y \end{array}$$

Since  $t$  and  $t'$  are quasi-isomorphisms, we can construct  $V$  by homotopy pullback such that the following diagram commutes up to homotopy. We define the addition  $\varphi + \varphi'$  to be the equivalence class of roofs of the form below.

$$\begin{array}{ccc} V & \xrightarrow{q'} & U' \\ q \downarrow & & \downarrow t' \\ U & \xrightarrow{t} & X \end{array} \qquad \begin{array}{ccc} & V & \\ t \circ q \swarrow & & \searrow g \circ q + g' \circ q' \\ X & & Y \end{array}$$

It is left to check that addition does define an additive structure, but we will skip the details.  $\square$

**Definition 1.17.** Let  $\mathbf{C}$  be a triangulated category. A collection  $S$  of morphisms in  $\mathbf{C}$  is said to be *compatible with triangulation* if

1.  $s \in S$  if and only if  $T(s) \in S$ .
2. consider the diagram (TR3), if  $f, g \in S$ , then the complementing morphism  $h \in S$ .

Derived categories can be triangulated. Let  $\mathbf{C}$  be a triangulated category and consider some localization  $\mathbf{C}_S$  that is compatible with triangulation. Define  $T$  to be the localizing functor and define  $\text{Ob}(\mathbf{C}_S) = \text{Ob}(\mathbf{C})$ . A triangle in  $\mathbf{C}_S$  is a image of a triangle in  $\mathbf{C}$  under the localization  $\mathbf{C} \rightarrow \mathbf{C}_S$ . This defines a triangulated category. See [Gel03] IV.2 for a detailed proof. It is not hard to check that  $\text{Qis}$  is compatible with  $\mathbf{K}(\mathbf{A})$ , hence  $\mathbf{D}(\mathbf{A})$  is triangulated.

**Definition 1.18.** Let  $\mathbf{A}$  be an abelian category and let  $\mathbf{K}^*(\mathbf{A})$  be a triangulated subcategory of  $\mathbf{K}(\mathbf{A})$ . If the natural functor  $\mathbf{K}^*(\mathbf{A})_{\mathbf{K}^*(\mathbf{A}) \cap \text{Qis}} \rightarrow \mathbf{D}(\mathbf{A})$  is fully-faithful, then  $\mathbf{D}^*(\mathbf{A})$  is called a *localizing subcategory* and we denote it by  $\mathbf{D}^*(\mathbf{A})$ .

We show the definition of a right derived covariant functor and the other definitions can be obtained similarly.

**Definition 1.19.** Let  $\mathbf{A}$  and  $\mathbf{B}$  be abelian categories. Let  $F : \mathbf{K}^*(\mathbf{A}) \rightarrow \mathbf{K}(\mathbf{B})$  be a  $\partial$ -functor. The *right derived covariant functor* of  $F$  is a  $\partial$ -functor  $R^*F : \mathbf{D}^*(\mathbf{A}) \rightarrow \mathbf{D}(\mathbf{B})$  together with a natural transformation  $\eta : Q \circ F \rightarrow R^*F \circ Q$  from  $\mathbf{K}^*(\mathbf{A}) \rightarrow \mathbf{D}(\mathbf{B})$  such that if  $G : \mathbf{D}^*(\mathbf{A}) \rightarrow \mathbf{D}(\mathbf{B})$  is a  $\partial$ -functor and  $\xi : Q \circ F \rightarrow G \circ Q$  is a natural transformation, then there exists unique natural transformation  $\eta' : R^*F \rightarrow G$  such that  $\xi = (\eta' \circ Q) \circ \eta$ .
